ABSTRACT

Visualizations of the full set of aggregate shapes studied in the paper “Sensitivity of Polarization to Grain Shape: II. Aggregates”, and wavelength dependence of extinction and polarization cross sections for every shape.

Keywords: interstellar dust (836), radiative transfer (1335)

1. INTRODUCTION

As described in Paper II (Draine 2024a), scattering and absorption cross sections have been calculated for a total of 45 targets. 42 of these targets were irregular aggregates nominally consisting of $N = 256$ equal-size spheres¹ generated using twelve different procedures. Paper II included images of one example of each type. Here we provide views of all 45 aggregates.

Paper II included figures showing the extinction and polarization cross sections as a function of wavelength λ for one example of each type. Here we provide figures showing the extinction and polarizations for every aggregate, for completeness.

2. AGGREGATES

All targets are assemblies of equal-sized spheres. Targets studied include $N = 2$ (“bisphere”, two touching spheres), two $N = 3$ examples (“trisphere” and “threesphere” geometry), and 42 $N = 256$ examples, generated by a total of nine different procedures.

Three of the procedures are the “BA”, “BAM1”, and “BAM2” random aggregation procedures described by Shen et al. (2008). In addition, Paper II discusses modification of these random aggregates to greater degrees of flattening or elongation by random aggregation followed by three different “trimming” procedures, denoted *trimA*, *trimB*, and *trimC* (see Paper II).

Figure 1 shows the $N = 2$ and $N = 3$ examples. Figures 2–11 show the $MN = 256$ aggregates studied.

Each of the targets in Paper II is shown from three orientations. Axis $\hat{\mathbf{a}}_1, \hat{\mathbf{a}}_2, \hat{\mathbf{a}}_3$ are the principal axes of largest, intermediate, and smallest moments of inertia. In perfect spinning alignment (PSA), the grain is spinning around $\hat{\mathbf{a}}_1$, and radiation is propagating perpendicular to $\hat{\mathbf{a}}_1$.

draine@astro.princeton.edu

¹ As explained in Paper II, one of the aggregates consisted of only $N = 203$ spheres as a result of the “trimming” procedure used.

Figure 1. Bisphere, threesphere, and trisphere geometries. The scale bars show $2a_{\text{eff}}$, the diameter of an equal-volume sphere. \hat{a}_1 is the principal axis of largest moment of inertia; grains are assumed to spin around this axis.

3. CROSS SECTIONS FOR EXTINCTION AND POLARIZATION

As described in Papers I and II, cross sections for absorption and scattering have been calculated for all of shapes in this study, for selected sizes $a_{\text{eff}} = 0.05, 0.10, 0.15, 0.20, 0.25, 0.30 \mu\text{m}$, and 251 wavelengths $\lambda \in [0.1 \mu\text{m}, 100 \mu\text{m}]$.

The computations were done using the discrete dipole approximation (DDA) code DDSCAT². Calculations were carried out using different numbers N_{dip} of dipoles to represent the target; the computed results are used to extrapolate to $N_{\text{dip}} \rightarrow \infty$, using Eq. (8) in Draine (2024b).

Uncertainties in the extrapolation are estimated by using calculations for three different N_{dip} [Eq. 9](Draine 2024b).

For all of the shapes studied in Paper II, Figures 14–25 show the dimensionless quantities $\lambda Q_{\text{ran}}/a_{\text{eff}}$ and $\lambda Q_{\text{pol,PSA}}/a_{\text{eff}}$, where Q_{ran} is the efficiency factor for extinction by randomly-oriented targets, and $Q_{\text{pol,PSA}}$ is the efficiency factor for polarization by particles in perfect spinning alignment.

$Q_{\text{ran}}(\lambda)$, $Q_{\text{pol,PSA}}(\lambda)$ and $Q_{\text{sca}}(\lambda)$ obtained by extrapolation are available in machine-readable form over the full wavelength range $0.1\text{--}100 \mu\text{m}$ at xxx [btd note: doi].

The DDSCAT parameter files used for these calculations are available at *url here*. Additional data are available from the author upon request.
